DAS_Group_19

1 Introduction

The question for Group 19 is: Which factors influence the number of days an animal spends in the shelter before their final outcome is decided

We start by viewing the whole data at first.

```
glimpse(animals)
```

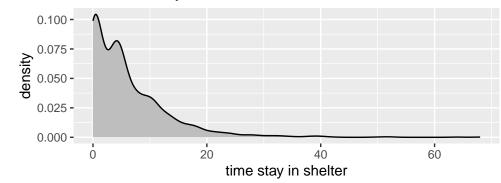

2 Exploratory Data Analysis

We need to choose which GLM should be used for the model by plotting the densities of manufacture (dependent variable y)

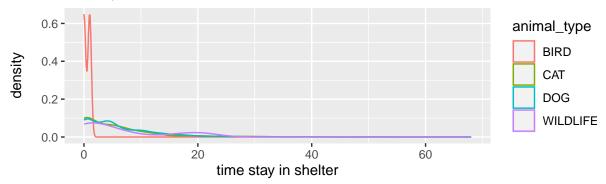

We first investigate what kind of density function y (time in the shelter) obeys

The overall density function of time at shelter and the density functions for different animals are plotted below.

overall density function of time at shelter

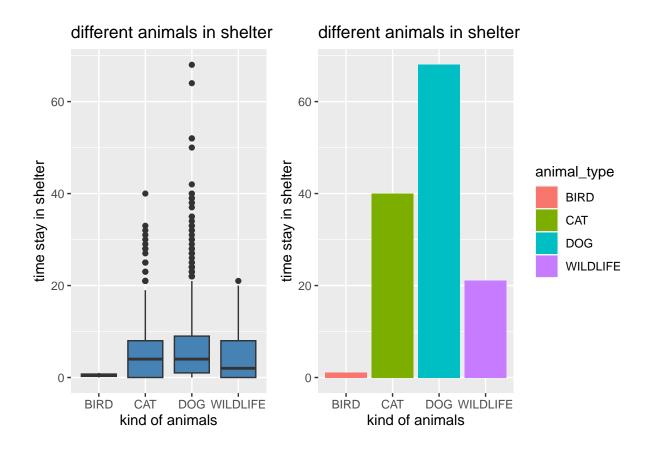

density functions for different animals

As we can see, these two graphs have shown a typical poisson distribution which give us the direction of using the **logit link function** combined with the assumption that the response y (time at shelter) obeys the **poisson distribution** for **GLM** method later on.

But we will still observe the distribution of each variable (via boxplots and histograms)

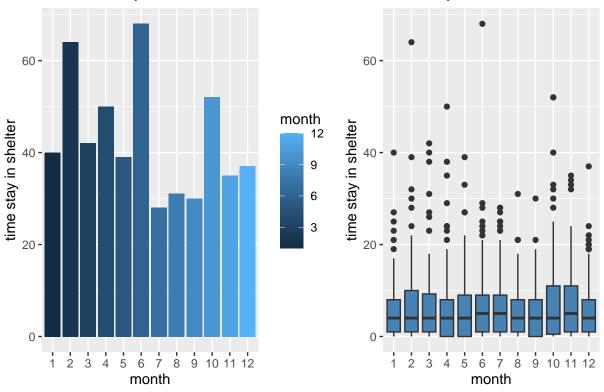

Observing the time at shelter for different kinds of animals.

Observing the time that animals stay in shelter in different month.

the summary of months in time in shelt

summary of month in time in s

After visualizing the data, we fond that there was no obvious changes but slightly different between the **first** half year and the **second half year** so we may classify time into two parts. (The month from 1 to 6 will be labelled as first half year and the month from 7 to 12 will be labelled as second half year)

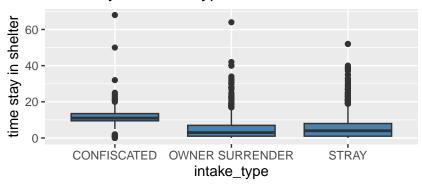

```
animals_used<-animals%>%
  mutate(time = ifelse(month > 6, "second half year", "first half year"))
```

Observing the time that animals stay in shelter related to intake type.

the summary of intake_type in time in shelter

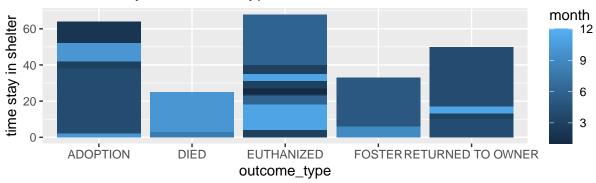

summary of intake_type in time in shelter

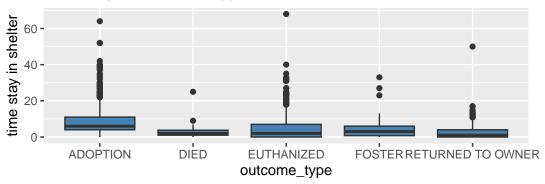

Observing the time that animals stay in shelter related to outcome type.

the summary of outcome_type in time in shelter

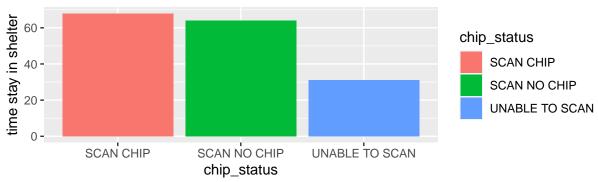

summary of outcome_type in time in shelter

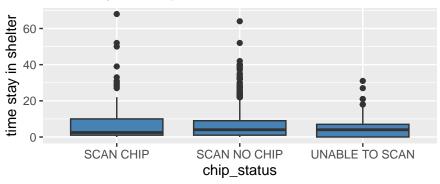

Observing the time that animals stay in shelter related to chip status.

summary of ochip_status in time in shelter

3 Model Analysis

After observing all the variables, we fond that there was no obvious linear relationship. But as we mentioned before, we can use **GLM** method with family=poisson(link="log") for fitting the data. And the formula we will use is given by:

$$\begin{aligned} y_i \\ \sim \\ Poisson\left(\lambda_i\right) \\ log\left(\lambda_i\right) &= \beta_0 + \beta_1 x_{1i} + \dots + \beta_j x_{ji} \\ \lambda_i &= exp\left(\beta_0 + \beta_1 x_{1i} + \dots + \beta_j x_{ji}\right) \\ \frac{\lambda_{ji}}{\lambda_0} &= exp\left(\beta_j\right) \end{aligned}$$

Where

and

where λ_{ji} is the value of λ_i when only x_{ji} is 1 and λ_0 is the exp of β_0 .

Since all the explanatory variables are characteristic, the exp of β_j means that the mean of y_i will be e^{β_j} times of the mean where the j_{th} factor changes from 0 to 1.

As a result, if the exp of coefficient is closer to 1, the more unlikely the factor will affect the response term. We first try the full model for fitting the whole data.

```
animals_used<-animals_used%>%
  select(-c("month"))
animals_used$year<-as.character(animals_used$year)</pre>
mod.loglinear <- glm(time_at_shelter ~ year + animal_type + intake_type + outcome_type + chip_status +</pre>

```

4 Conclusion

We then conclude that the factors: intake type and outcome type affect the time at shelter the most.

Residuals can be seen as follow the assumption. Actually, the residuals should follow the assumptions theoretically by the theory of GLM.

```
animals_used <- animals_used %>%
  mutate(counts_pred = fitted(mod.loglinear_alt))
p1<-ggplot(mod.loglinear_alt, aes(x = mod.loglinear_alt$residuals))
p1 + geom_boxplot(color = "black", fill = "gray")</pre>
```
